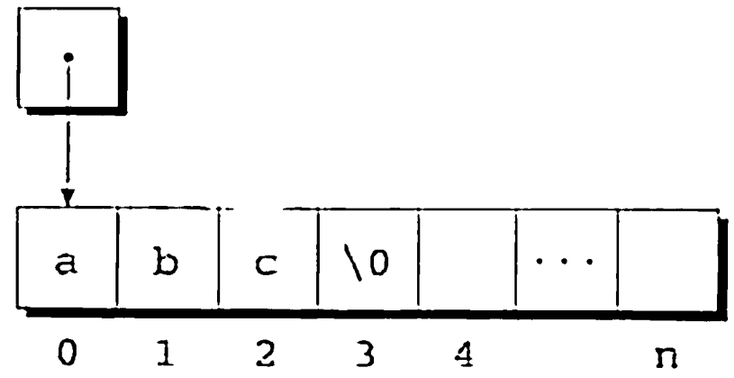
Calling `strcpy` is one way to initialize this array:

```
strcpy(p, "abc");
```

The first four characters in the array will now be `a`, `b`, `c`, and `\0`:



Using Dynamic Storage Allocation in String Functions

Dynamic storage allocation makes it possible to write functions that return a pointer to a "new" string—a string that didn't exist before the function was called. Consider the problem of writing a function that concatenates two strings without changing either one. C's standard library doesn't include such a function (`strcat` isn't quite what we want, since it modifies one of the strings passed to it), but we can easily write our own.

Our function will measure the lengths of the two strings to be concatenated, then call `malloc` to allocate just the right amount of space for the result. The function next copies the first string into the new space and then calls `strcat` to concatenate the second string.

```
char *concat(const char *s1, const char *s2)
{
  char *result;

  result = malloc(strlen(s1) + strlen(s2) + 1);
  if (result == NULL) {
    printf("Error: malloc failed in concat\n");
    exit(EXIT_FAILURE);
  }
  strcpy(result, s1);
  strcat(result, s2);
  return result;
}
```

If `malloc` returns a null pointer, `concat` prints an error message and terminates the program. That's not always the right action to take; some programs need to recover from memory allocation failures and continue running.

Here's how the `concat` function might be called:

```
p = concat("abc", "def");
```

After the call, `p` will point to the string `"abcdef"`, which is stored in a dynamically allocated array. The array is seven characters long, including the null character at the end.
